SPECIFICATION

To all whom it may concern:

Be It Known, That we, **Craig E. Maddox** and **Daniel F. White**, citizens of the United States of America, both residing at Lilburn, Georgia, have invented certain new and useful improvements in a **CASH DRAWER BILL DISPENSER**, of which I declare the following to be a full, clear and exact description:

1 CASH DRAWER BILL DISPENSER

2 BACKGROUND OF THE INVENTION

3 The present invention relates generally to cash registers, and, more
4 specifically, to cash drawers therein.

5 A cash register includes a drawer having several compartments or bins in
6 which are stored various denominations of paper currency bills and metallic
7 coins. A typical cash drawer is in the form of a removable till containing the
8 bins, and each of the bins for the paper bills includes a bill holder which sits atop
9 a stack of bills therein.

10 Bill holders come in various configurations and typically include a
11 cantilever or flapper which is spring loaded and positionable in an up position for
12 allowing access to the bin for adding or removing bills, and in a down position
13 providing a compression force atop the stack of bills to maintain them in place.

14 However, in order for a clerk to add or remove bills from the bins, the bill
15 holder must be lifted up for allowing one or more bills to be inserted or removed
16 from the bins.

17 Accordingly, it is desired to improve the bill holder to perform the
18 additional function of at least dispensing individual bills without lifting the bill
19 holder.

2

1 BRIEF SUMMARY OF THE INVENTION

2 A bill dispenser includes a cantilever and traction wheel attached thereto.
3 The wheel includes a traction surface around a perimeter thereof for frictionally
4 engaging a currency bill. Movement of the traction surface atop the bill is used
5 for dispensing the bill from its bin.

6 BRIEF DESCRIPTION OF THE DRAWINGS

7 The invention, in accordance with preferred and exemplary embodiments,
8 together with further objects and advantages thereof, is more particularly
9 described in the following detailed description taken in conjunction with the
10 accompanying drawings in which:

11 Figure 1 is an isometric view of an exemplary cash register having a cash
12 drawer with a bill dispenser in accordance with an exemplary embodiment of the
13 present invention.

14 Figure 2 is a top, plan view of one of several bill compartments in the cash
15 drawer illustrated in Figure 1 and taken along line 2-2 showing a bill dispenser
16 in accordance with an exemplary embodiment of the present invention.

17 Figure 3 is a side elevational view, partly in section of the bill dispenser
18 in the compartment illustrated in Figure 2 and taken along line 3-3.

19 Figure 4 is an isometric view of the bill dispenser illustrated in Figure 2 in
20 a lifted or raised position for allowing access into the bill compartment.

21 Figure 5 is a top, plan view of a bill compartment including a bill dispenser
22 in accordance with an alternate embodiment of the present invention.

23 Figure 6 is a side elevation view, partly in section of the bill dispenser
24 illustrated in Figure 5 and taken along line 6-6.

25 Figure 7 is an enlarged view of an exemplary traction wheel of the bill
26 dispenser illustrated in Figures 5 and 6.

DETAILED DESCRIPTION OF THE INVENTION

1

2 Illustrated in Figure 1 is a cash register 10 which may take any
3 conventional form for a typical Point Of Sale (POS) terminal for example. The
4 register 10 includes a cash drawer 12 which automatically is ejected open when
5 required by the register in a typical sales transaction to expose a plurality of
6 currency compartments or bins 14 therein. One group of the bins 14 is arranged
7 in a back row configured in width, length, and depth for storing flexible paper
8 currency bills 16 in corresponding denominations. A front row of smaller bins
9 is provided for storing metallic coins in various denominations typically aligned
10 with respective ones of the rear bins. The cash drawer 12 is typically in the
11 form of a removable tray or till which may be metal or plastic having integral
12 dividers which define the several bins 14.

13 As shown generally in Figure 1 and in more detail in Figure 2, each of the
14 bins 14 configured for storing the currency bills 16 includes a respective bill
15 holder and dispenser 18 in accordance with an exemplary embodiment of the
16 present invention. The dispenser 18 provides a clamping force in its down
17 position to hold a stack of bills in the bin, and also allows improved manual
18 dispensing of individual bills by a clerk when desired. The dispenser 18 also has
19 an up or lifted position for replenishing the stack of bills in the corresponding
20 bins, or removing groups of the bills if desired.

21 The bill dispenser 18 is illustrated in more detail in Figures 2 and 3 and
22 includes a frame in the form of a cantilever 20 having a base 20a at a proximal
23 end which is pivotally mounted in the bin to freely suspend a tip 20b at an
24 opposite distal end thereof. A traction wheel 22, which is preferably made of
25 rubber, is pivotally attached to the cantilever adjacent the tip, and includes a
26 traction surface 22a around a perimeter thereof for frictionally engaging and
27 dispensing individual ones of the bills 16 in contact therewith.

28 The traction wheel 22 may be suitably incorporated in any type of

4

1 conventional bill holder for converting it to the additional purpose of bill
2 dispensing. For example, the cantilever 20, but for the incorporated traction
3 wheel 22, is otherwise conventional and may be configured and operated in a
4 conventional manner like that found in U.S. Patent 3,892,309, assigned to the
5 present assignee. As shown in Figures 2 and 3, the cantilever 20 is pivotally
6 attached to a corresponding removable mounting bracket 24. The base of the
7 bracket 24 is configured for being removably mounted in a corresponding slot at
8 the back of the till 12 for assembly and replacement purposes.

9 The bracket 24 includes a pair of outboard arms having side apertures at
10 distal ends thereof which receive corresponding mounting pins disposed at the
11 base end in corresponding outboard arms of the cantilever 20 for pivotally
12 mounting the cantilever to the bracket. The bracket 24 also includes a center
13 portion between the outboard arms having an inclined distal end which forms a
14 cantilever leaf spring. The base of the cantilever 20 has a corresponding center
15 portion configured in the form a cam which engages the leaf spring on the
16 bracket. The cantilever 20 has a down position atop the stack of bills 16 as
17 shown in Figure 3 maintained by spring force from the bracket leaf spring against
18 the cam of the cantilever. The cantilever also has a raised or up position
19 illustrated in phantom line in Figure 3 and in solid line in Figure 4 which extends
20 generally perpendicularly upwardly from the bills in the bins for allowing access
21 thereto, with the up position being maintained by the spring force on the cam at
22 the cantilever base.

23 As shown in Figures 3 and 4, means are provided for manually engaging
24 the traction surface 22a against the top bill 16 in the bin 14 for translation
25 thereof to the front of the bin to eject the bill at least in part therefrom. In the
26 exemplary embodiment illustrated, the engaging means include pivotally
27 attaching the traction wheel 22 to the cantilever for selective rotation manually
28 by the clerk. This is effected by providing a housing or frame 26 attached to the
29 bottom of the cantilever 20 for mounting the traction wheel 22 centrally therein

5

1 using a center shaft 28. The shaft 28 allows the wheel to be manually rotated
2 on the otherwise stationary cantilever 20 for use in dispensing individual bills in
3 turn with the cantilever in its down position atop the bills. The traction wheel
4 22 provides a compressive holding force atop the stack of bills for functioning
5 as a typical bill holder, yet when the traction wheel 22 is manually rotated,
6 individual bills may be dispensed.

7 More specifically, in the exemplary embodiment illustrated in Figures 3 and
8 4, the engaging means preferably also include a plurality of circumferentially
9 spaced apart recesses or notches 30 in the perimeter of the traction wheel which
10 separate the traction surface 22a into a corresponding plurality of circumferential
11 segments at the top of corresponding teeth. The notches 30 are sized and
12 configured for manually rotating the wheel by finger to engage the traction
13 surface segments in turn upon an individual bill for sequential translation thereof.

14 As shown in Figure 3, by spinning the traction wheel 22 in the
15 counterclockwise rear direction illustrated, the top bill 16 can be dispensed
16 forwardly inside the bin 14. The spring force from the bracket 24 provides some
17 downward force upon the traction wheel 22, and the manual spinning thereof
18 by a clerk provides additional downward force which effects frictional
19 engagement between individual ones of the traction surfaces 22a in contact with
20 the top of the bill 16 for sliding it forwardly atop the next underlying bill in the
21 stack.

22 In the preferred embodiment, the individual notches 30 are about as wide
23 as corresponding ones of the traction surfaces 22a along the circumferential
24 direction on the perimeter of the wheel for both providing sufficient space for
25 inserting a finger in a notch 30 and improving the traction effect of the surfaces
26 22a. Each traction surface 22a is preferably generally flat or slightly convex and
27 has a corresponding, generally sharp leading edge which first contacts the top
28 of a bill as the wheel is rotated. The traction surface 22a, and preferably the
29 entire wheel, is formed of a suitable traction material such as rubber for effecting

1 a frictional dispensing force F , as illustrated in Figure 3, as the wheel is rotated
2 or spun for dispensing the bills. Although the notches 30 may be eliminated in
3 an alternate embodiment, see below, having a circumferentially continuous
4 traction surface 22a, in the preferred embodiment the relatively large notches 30
5 are preferred for maximizing the ease of use and bill dispensing capability of the
6 traction wheel 22.

7 As shown in Figure 3, the traction wheel 22 includes a bottom having a
8 respective one of the traction surfaces 22a engaging the top of the bill 16, and
9 the cantilever tip 20b defines a guide having a predetermined vertical gap relative
10 to the wheel bottom and bill top for guiding the bill upon dispensing thereof.
11 The cantilever tip 20b does not normally contact the top of the bills, which
12 instead are held in place by the traction wheel 22 itself. The cantilever guide
13 20b is positioned instead to guide individual bills being dispensed to prevent
14 excessive vertical movement or buckling thereof during the dispensing process.

15 Since the bill dispenser 18 is configured for specific use in combination
16 with the till 12, the corresponding bins 14 are preferably modified to include an
17 arcuate front ramp 32 as shown in Figure 3 which is generally concave for
18 turning or guiding upwardly the leading edge of the bills as they are being
19 dispensed. As the traction wheel 22 is rotated to dispense an individual bill
20 forwardly in the bin 14, the leading edge of the bill engages the ramp 32 and is
21 guided upwardly so that it is conveniently positioned for being manually grabbed
22 and removed the clerk.

23 Furthermore, the front ramp 32 as shown in Figure 2 is preferably knurled
24 or rough in texture using exemplary crossing score lines 34 to frictionally restrain
25 underlying bills as a top bill is being dispensed. In the event the traction wheel
26 22 dispenses more than the top bill due to excessive friction between the top bill
27 and underlying bills, the underlying bills will engage the scores 34 on the ramp
28 32 and meet additional frictional resistance for improving the dispensing of only
29 the single top bill from the bin.

7

1 The introduction of the traction wheel 22 into the cantilever 20 is a
2 relatively simple modification which maintains the bill holding capability of the
3 cantilever by the traction wheel 22 itself, yet also provides the additional
4 function of manual bill dispensing by simple rotation of the traction wheel when
5 desired. The bill dispenser 18 is simply operated by lowering the cantilever 20
6 to position the traction wheel 22 atop the stack of bills, and then manually
7 rotating and pressing downwardly the traction wheel in a rearward direction from
8 the top thereof to partially dispense the top bill forwardly. The wheel 22 is
9 rotated as much as necessary to move the bill forwardly in the bin and up the
10 ramp 32 until it is in position for being manually removed by the clerk.

11 An additional advantage of operating the bill dispenser 18 is that the
12 partially dispensed bill may then be manually pulled by the clerk which in turn
13 automatically and additionally rotates the traction wheel 22 by friction from the
14 pulled bill, which autofeeds the next lower bill directly beneath the bill being
15 dispensed. As the top bill is yanked from the bin 14, the weight of the traction
16 wheel 22 itself sitting atop the bill maintains sufficient frictional engagement
17 force therewith which causes the wheel to rotate further by pulling of the bill
18 thereunder. Inertia of the traction wheel 22 causes additional rotation thereof
19 which partially ejects the underlying bill. The traction wheel may then be
20 additionally turned if desired for further dispensing that bill, or that bill may be
21 manually grabbed and pulled by the clerk autofeeding yet another underlying bill.

22 In a preferred embodiment, the traction wheel 22 is freely rotatable in
23 opposite directions on its shaft 28 so that a clerk may rotate the wheel in a
24 forward or clockwise direction, see Figure 3, to reinsert any partially dispensed
25 bill if desired, or to resupply the bin with bills individually without lifting the
26 cantilever 20.

27 The relatively simple traction wheel 22 may be readily incorporated into
28 various forms of bill holders for use therewith. It therefore minimizes the
29 required changes in the bill holder and has relatively low cost. And, most

8

1 significantly, it provides the ability to dispense individual bills from the bins in a
2 simple manner without lifting the bill dispenser itself.

3 Another form of the bill dispenser, designated 36, is illustrated in Figures
4 5-7. In this embodiment, the cantilever, designated 38, is pivotally attached at
5 its proximal, base end to a corresponding tip end of a base lever 40 defining a
6 second cantilever having a root end pivotally mounted by a shaft 42 extending
7 through a pair of vertical slots 44 in the till. The shaft 42 and slots 44 allow the
8 articulated cantilever 38 and base lever 40 to be pivoted together upwardly for
9 allowing unobstructed access into the corresponding bin ¹⁴~~44~~ while allowing the
10 assembly to be lowered atop the stack of bills 16 irrespective of the height of
11 the bill stack.

12 A tension coil spring 46 extends between the base lever and cantilever
13 and is attached thereto at opposite ends thereof. The cantilever and base lever
14 are joined together in a generally inverted V-shape with an obtuse joining angle
15 therebetween, and the spring 46 provides retraction force to pull the distal end
16 of the cantilever 38 toward the root end of the base lever 40 for minimizing that
17 obtuse angle.

18 A push button or pad 48 is provided or defined atop one of the levers
19 38,40 near the intersection point thereof for manually depressing downwardly
20 both levers against the retraction force from the spring to translate the traction
21 wheel, designated 50, atop the bill 16 for dispensing thereof.

22 In the first embodiment disclosed above, the traction wheel 22 is freely
23 rotatable, and is manually rotated for dispensing an individual bill. In the
24 alternate embodiment illustrated in Figures 5-7, the traction wheel 50 has a
25 different, clutch wheel form and preferably does not rotate during the dispensing
26 operation, with its perimeter traction surface 50a instead engaging the bill 16
27 using the articulated cantilever 38 and base lever 40 in a pumping manner.

28 More specifically, the means for manually engaging the traction surface
29 50a against the bill for translation thereof further include a ratchet in the form

9

1 of a wheel 52 suitably attached to the traction wheel 50, and a corresponding
2 pawl 54 pivotally attached to the cantilever 38 and operatively engaging the
3 ratchet 52. The ratchet 52 and pawl 54 prevent forward, clockwise rotation of
4 the traction wheel 50 upon depression of a push pad 48, and permit only one
5 way, reverse, counterclockwise rotation of the traction wheel upon release of
6 the pad 48.

7 The ratchet and pawl allow unrestrained reverse rotation of the traction
8 wheel 50 as the cantilever 38 is retracted atop the stack of bills. In this way,
9 reverse frictional force is not created which would return the dispensed bill to its
10 original position atop the stack. The free reverse movement of the traction
11 wheel 50 also allows individual bills to be yanked by the clerk and removed from
12 below the traction wheel without resistance therefrom.

13 The bill dispenser 36 illustrated in Figures 5-7 is operated by initially
14 lowering the levers 38,40 into the bin 14 for placing the traction wheel 50 atop
15 the stack of bills 16. Then by manually pushing or depressing the push pad 48
16 downwardly, the cantilever 38 and base lever 40 are extended in collective
17 length against the retraction force from the spring 46 which translates forwardly
18 the traction wheel 50 for frictionally engaging and dispensing at least in part the
19 top bill 16. Since this downward pumping action of the two levers 38,40
20 translates the traction wheel 50 toward the front of the bin 14, the ratchet and
21 pawl prevent forward rotation of the wheel for effecting frictional engagement
22 of the wheel with the bill 16 for dispensing thereof.

23 Upon removing the depression force from the push pad 48, the retraction
24 spring 46 is allowed to retract the cantilever 38 against the base lever 40 by
25 pivoting around the intermediate joint therebetween. In the preferred
26 embodiment illustrated in Figure 6, an integral tab 56 is attached to the distal
27 end of the base lever 40 and is configured in arcuate extent to provide an
28 abutment stop to limit the retraction of the cantilever 38 against the base lever
29 40 while allowing unobstructed extension of the cantilever 38 therefrom.

1 In a preferred embodiment, the traction wheel 50 is circumferentially
2 continuous and the traction surface 50a thereof has suitable frictional
3 performance and may be formed of rubber for example. The traction surface
4 50a may have small ribs for maximizing frictional engagement with the bills
5 during dispensing.

6 In the exemplary embodiment illustrated in Figure 5, for example, a pair
7 of the traction wheels 50 are fixedly attached to a common through-shaft 58
8 and straddle the distal end of the cantilever 38. The ratchet 52 may be attached
9 to the side of one of the traction wheels and the pawl 54 may be pivotally
10 attached to an intermediate portion of the cantilever 38 for engaging the ratchet
11 52.

12 In the preferred embodiment illustrated in Figures 5 and 6, the bill
13 dispenser also includes a cooperating fork 60 pivotally mounted at its base end
14 to the bin, preferably at the root end of the base lever using the common shaft
15 42. The fork includes a pair of spaced apart fork arms which support the
16 traction wheels 50 when lifted by extending the opposite ends of the shaft 58
17 to rest thereatop as illustrated in Figure 5. As shown in Figure 6, the bottom of
18 the traction wheels 50 extend below the fork 60 for engaging the stack of bills
19 therebelow. In this way, the cantilever 38 may be lifted alone, or by lifting the
20 fork 60, and may be pumped for bill dispensing without obstruction from the
21 fork.

22 The distal ends of the arms of the fork 60 as illustrated in Figure 6
23 preferably define a predetermined vertical gap relative the bottom of the traction
24 wheels 50 and the top bill for guiding the bill upon dispensing in a manner similar
25 to the cantilever tip 20b described above in the first embodiment. Similarly, the
26 bin 14 may also include the arcuate ramp 32 which cooperates with the bill
27 being dispensed for guiding it upwardly for being grabbed by the clerk.

28 The first embodiment of the bill dispenser 18 illustrated in Figure 2-4
29 provides simplicity and ease of use by simply manually spinning the notched

11

13 Accordingly, what is desired to be secured by Letters Patent of the United
14 States is the invention as defined and differentiated in the following claims:
